

## 213 mt notes

\* references must be initialized during declaration.

\* const functions cannot call any other functions which are not const.

heap = segment of the memory where dynamic memory allocation takes place.

delete array  $\Rightarrow$  delete [] arr;

:: scope resolution operator  $\Rightarrow$  can also be used to a global variable which has a local variable with the same name.

the reason of using namespaces in C++

$\hookrightarrow$  two different libraries might use the same label for a class or variable

struct in C++

- can have private members
- can have member functions
- the default access modifier is public

\* the default members of C++ class are private, if you try to access them, you get compile error.

namespace

```
namespace ceng {
    class pair {
        int a, b;
    };
}
```

$\Rightarrow$  ceng::pair p;

"using" keyword is used to indicate which namespace to search to find classes and variables

\* std is the namespace of the C++ standard library.

void data type in C++

indicates an absence of data. means "no value" or "nothing"

★ if you try to call empty constructors like `class_name obj();` you get a compile error `class_name obj; ✓`

## Default methods in C++

### 1- default constructor

can be called with no arguments (if the user defines a constructor, it is not provided)

### 2- destructor

called automatically when the object goes out of scope:

- the function ends
- the program ends
- a block containing local variables ends
- a delete operator is called

### 3- copy constructor

called with a reference to a class instance as an argument

### 4- copy assignment operator

equivalent to an assignment operator that assigns every member of its argument to a corresponding member of this instance

```
myclass a, b;
```

// copy constructor is called

```
myclass c = a;
```

// copy assignment operator is called

```
b = a;
```

• Copy constructor = when new object is created.

• assignment operator = when an existing obj is assigned to a new object

## constant variables

- their values never change
- must be initialized when defined

built-in types = fundamental types

$p \rightarrow a \equiv (*p).a$

## Syntax

• `classname(int a): x(a) {}` (no semicolon)

• `const classname & operator = (const classname & rhs) {  
    this->x = rhs.x;  
    return *this;  
}`

```
class classname {  
    int x;  
};
```

ambiguity = uncertainty

## C++ function overloading

if the number and/or type of arguments passed is different

★ they may or may not have different return types.

`(int x)` and `(int x, int y = 0)` are same for the compiler (because of initialization)

`x[]`  $\equiv$  `*x`

## vector declaration

`std::vector<int> v;`

### reverse order with recursion

```
fun (*a) {  
    if (a == null)  
        return;  
    else  
        fun(a->next);  
    cout << a;  
}
```

### reverse in queue

```
fun (*q) {  
    int i;  
    if (not_empty) {  
        i = q.dequeue();  
        fun(q);  
        q.enqueue(i);  
    }  
}
```

### linked list

#### Singly / without tail pointer

insert =  $O(n)$  (at the end)

finding  $x$ th element from beginning =  $O(1)$

from ending =  $O(n)$

count elements =  $O(n)$

### infix

$((a \times b) + (c / d))$

$((a * (b + c)) / d)$

$(a * (b + (c / d)))$

### postfix

$((a b x) (c d /) +): a b x c d / +$

$((a (b c +) *) d /): a b c + * d /$

$(a (b (c d /) +) *): a b c d / + *$

### prefix

$(+(x a b) (/ c d)): + * a b / c d$

$(/( * a (+ b c)) d): / * a + b c d$

$(* a (+ b (/ c d))) : * a + b / c d$

### queue

#### circular array

enqueue =  $O(1)$

20

last index

circular max<sup>h</sup> array

### tree

preorder: root-left-right

→ 8-5-9-7-1-12-2-4-11-3

inorder: left-root-right

→ 9-5-1-7-2-12-8-4-3-11

postorder: left-right-root

→ 9-1-2-12-7-5-3-11-4-8

binary tree:

find an element  $O(n)$

full binary tree: nodes either have two children or none.

avl tree:

- We choose avl tree over a binary search tree, to guarantee  $O(\log n)$  time operations on the tree
- after any operation, a avl tree can always be balanced

minimum height:  $\lfloor \log_2(n) \rfloor$
